1. B The positive section of  $f(x)$  consists of two segments, connection  $(0, 0)$  to  $(3, 3)$  to (4, 0). The area under any probability density function must be 1. However, the area under the positive section of  $f(x)$  is  $\frac{1}{2} \cdot 4 \cdot 3 = 6$ , so  $a = \frac{1}{6}$  $\frac{1}{6}$ .

2. C 
$$
E(x) = \int_0^4 xp(x) dx = \frac{1}{6} \left( \int_0^3 x^2 dx + \int_3^4 x(12 - 3x) dx \right)
$$
  
=  $\frac{1}{6} \left( \left[ \frac{1}{3} x^3 \right]_0^3 + \left[ \frac{12}{2} \right]^2 - \frac{3x^3}{3} \right]_3^4 = \frac{1}{6} \left( 9 + (96 - 64) - (54 - 27) \right) = \frac{7}{3}$ 

- 3.  $E = \frac{10!}{2 \times 10!}$  $rac{10!}{2!2!} = \frac{11!}{44}$  $\frac{11!}{44}$ , so  $n = 44$ .
- 4. D Pretending the word consist of 4 distinct consonants and 2 distinct vowels, the number of arrangements would be  $4 \cdot 3 \cdot 4!$ . However, with 2 each of Z and G, there are four copies of each arrangement. So the number of distinguishable ones is 72.
- 5. C If the point is selected above  $y = x^2$ , no tangent line can be drawn. If the point is selected below, two tangent lines can be drawn. The region has an area of 16. With an area of 2  $\int_0^2 x^2$  $\int_0^2 x^2 dx = 2 \left( \frac{x^3}{3} \right)$  $\frac{1}{3}$ <sub>0.</sub>  $2<sup>1</sup>$  $= \frac{16}{3}$  $\frac{16}{3}$ . So the expected value is  $0 \cdot \frac{2}{3} + 2 \cdot \frac{1}{3} = \frac{2}{3}$ .  $\frac{2}{3}$ .
- 6. D The sum of coefficients is  $4^{24} = 2^{48}$ . So as long as  $b > 0$  and  $b/48$ , there is a corresponding value for  $a$ .  $48 = 2^4 \cdot 3$ , so it has 10 factors, only two of which are odd. If  $b$  is even, there are two values of  $a$  (positive and negative), and if  $b$  is odd, there is only one. So there are a total of  $2 \cdot 8 + 1 \cdot 2 = 18$  ordered pairs.
- 7. E There are a few ways to create the constant term, arranged in decreasing powers of 1:  $1^{10} + \frac{10!}{1!7!7}$  $\frac{10!}{1!7!2!} (x^2)^1 (1)^7 \left(\frac{1}{x}\right)$  $\left(\frac{1}{x}\right)^2 + \frac{10!}{2!4!4}$  $\frac{10!}{2!4!4!} (x^2)^2 (1)^4 \left(\frac{1}{x}\right)$  $\left(\frac{1}{x}\right)^4 + \frac{10!}{3!1!6}$  $rac{10!}{3!1!6!}$   $(x^2)^3(1)^1\left(\frac{1}{x}\right)$  $\left(\frac{1}{x}\right)^6 = 4351.$
- 8. C An integer is relatively prime to 50 but not 36 if it is a multiple of 3 but not of 2 or 5. So of 6000 integers,  $\frac{1}{3}$  of which are multiples of 3,  $\frac{1}{2}$  of which are not multiples of 2, and  $\frac{4}{5}$  of which are not multiples of 5. In total, there are 6000  $\left(\frac{1}{3}\right)$  $\binom{1}{3} \binom{4}{2} \binom{4}{5} = 800$ numbers satisfying the condition.

9. B Consider the gaps between consecutive vertices. For instance, a gap of 1 means the two vertices are adjacent, where a gap of 6 means the two points are diametrically opposed. To count the number of incongruent quadrilaterals, we need to consider all partitions of 12 into 4 positive integers. The partitions are: 9111, 8211, 7311, 7221, 6411, 6321, 6222, 5511, 5421, 5331, 5322, 4431, 4422, 4332, 3333. If a partition is of the form AAAA or AAAB, there is only one possible quadrilateral. There are 3 such partitions, for 3 quadrilaterals. If a partition is of the form AABB or AABC, there are 2 possible quadrilaterals, where the two sides of gap A can be adjacent or opposite. There are 10 such partitions, for 20 quadrilaterals. If a partition is of the form ABCD, there are 3 possible quadrilaterals, where the opposite of A can be B, C, or D. There are 2 such partitions, for a total of 6 quadrilaterals. In total, there are 29 possible quadrilaterals.

10. D The probability is 
$$
\frac{3 \cdot 4 \cdot 5}{\frac{12}{3}} = \frac{3}{11}
$$
.

- 11. B As  $\theta$  ranges from 0 to  $2\pi r = 0$  when  $\theta = \frac{2\pi}{3}$  $\frac{2\pi}{3}, \frac{4\pi}{3}$  $\frac{m}{3}$ . The probability is the area of the inner loop over the area of the outer loop. The area of the outer loop is  $2 \cdot \frac{1}{2} \int_0^{\frac{2\pi}{3}} (1 + 2 \cos \theta)^2$  $\int_{0}^{\frac{2\pi}{3}} (1 + 2\cos\theta)^2 d\theta = \int_{0}^{\frac{2\pi}{3}} (1 + 4\cos\theta + 4\cos^2\theta)$  $\int_0^{\sqrt{3}} (1 + 4 \cos \theta + 4 \cos^2 \theta) d\theta$  $= \int_0^{\frac{2\pi}{3}} (1 + 4 \cos \theta + 2(\cos 2\theta + 1))$  $\int_{0}^{\frac{2\pi}{3}} (1 + 4\cos\theta + 2(\cos 2\theta + 1)) d\theta = [3\theta + 4\sin\theta + \sin 2\theta]_{0}^{\frac{2\pi}{3}} = 2\pi + \frac{3\sqrt{3}}{2}$  $\frac{\sqrt{3}}{2}$ The area of the inner loop is  $2 \cdot \frac{1}{2} \int_{\frac{2\pi}{3}}^{\pi} (1 + 2 \cos \theta)^2$  $\frac{\pi}{a^2}(1+2\cos\theta)^2 d\theta = [3\theta+4\sin\theta+\sin 2\theta]_{\frac{2\pi}{3}}^{\frac{\pi}{2}}$ య  $\frac{\pi}{2\pi} = \pi - \frac{3\sqrt{3}}{2}$  $\frac{\sqrt{3}}{2}$ Finally, the probability is  $\frac{2\pi-3\sqrt{3}}{4\pi+3\sqrt{3}}$
- 12. C There are 13 ways to select the value of the three of a kind, and 4 ways to choose their suits. There are 12 ways to select the value of the pair, and 6 ways to choose their suits. There are  $13 \cdot 4 \cdot 12 \cdot 6 = 3744$  different full houses.
- 13. E The probability of drawing a pair of matching socks is  $\frac{a(a-1)+b(b-1)}{(a+b)(a+b-1)} = \frac{1}{2}$  $\frac{1}{2}$ . Expanding to get  $2a^2 - 2a + 2b^2 - 2b = a^2 + 2ab + b^2 - a - b$ , Collecting to get  $a^2 - 2ab + b^2 - a - b = 0$ , or  $(a - b)^2 = a + b$ . In other words,  $a + b$  must be a perfect square. Let  $n = a - b$ , we can consider the system  $a + b = n^2$ ,  $a - b = n$ , which has solutions  $a = \frac{n^2 + n}{n}$  $\frac{n^2+n}{2}$ ,  $b=\frac{n^2-n}{2}$ .  $\frac{-n}{2}$ . Since *a*, *b* are even integers, it follows that  $n$  must be a multiple of 4. The third smallest possible value of *n* then is 12, making  $a + b = 144$ .
- 14. B Consider any interval  $[a, b]$ , if a value of x is selected at random, then the expected height is  $\frac{1}{b-a} \int_a^b x^3$  $\int_a^b x^3 dx$ , and the corresponding rectangular approximation for the interval would have an expected area of  $\int_a^b x^3$  $\int_a^b x^3 dx$ . In other words, a Riemann sum approximation done in this manner simply has expected area of  $\int_0^4 x^3$  $\int_0^4 x^3 dx = 64.$
- 15. D There are 40 students taking at least one of the two classes, and 25 + 30 − 40 = 15 students taking both classes. So the probability is  $\frac{15}{40} = \frac{3}{8}$  $\frac{5}{8}$ .
- 16. B Consider consecutive terms in the expansion, they would look like  $\binom{31}{1}$  $\binom{n}{n} x^n 2^{31-n}$ and  $\binom{31}{n-1} x^{n-1} 2^{31-n+1}$ . So the ratio of coefficients is  $\frac{\binom{31}{n-1} 2^{31-n}}{\binom{31}{n} 2^{31-n}}$  $\frac{(n-1)^{2^{31-n}}}{(31)2^{31-n}} = \frac{2n}{32-n}$ simply need to determine the last value of *n* such that  $\frac{\binom{n}{2}}{32-n} > 1$ , indicating an  $rac{2n}{32-n}$ . We increase in coefficient. This occurs at  $n = 11$ , indicating an increasing exponent from  $x^{11}$  term to  $x^{10}$  term, and  $x^{10}$  term has the greatest coefficient.
- 17. C Let  $\frac{DE}{DC} = x$ , then x ranges from 0 to 1, as E moves from D to C.  $ΔDEN ~ ∞ ΔBAN, so <sup>DN</sup> <sub>PN</sub>$  $rac{DN}{BN} = x$ , and  $rac{MN}{BD} =$  $1+x$  $\frac{1}{2}$  - x  $\frac{2}{2-x} = \frac{1-x}{2+2x}$  $\frac{1-x}{2+2x}$ . Since  $\triangle MAN$  and  $\triangle BAD$  share a height from vertex  $A$ , the ratio of their areas is simply a ratio of the bases  $MN$  and BD.  $[BAD] = \frac{1}{2}$  $\frac{1}{2}[ABCD] = 60$ , so  $[MAN] = 30\left(\frac{1-x}{1+x}\right)$ . The expected area is then 30  $\int_0^1 \frac{1-x}{1+x}$  $1+x$  $\mathbf 1$  $\int_0^1 \frac{1-x}{1+x} dx = 30 \int_0^1 \left( -1 + \frac{2}{1+x} \right)$  $\int_{0}^{1} \left( -1 + \frac{z}{1+x} \right) dx$  $= 30[-x + 2 \ln(1 + x)]_0^1 = 30(2 \ln 2 - 1)$
- 18. A  $\frac{7!}{2!}$  $\frac{1}{2!3!2!}$  = 210
- 19. E In general, the graph is isomorphic to the vertices and edges of an octahedron, which may be a helpful way of visualizing the paths. For this question in particular, the first edge must lead from A to one of B, C, E, F. All four of those vertices are in equivalent positions with respect to A and D, so without loss of generality, let the first edge be  $AB$ . From B, the next vertex can be  $D, C, F$ . D ends the path. We can consider traveling to  $C$ ,  $F$  as traveling clockwise or counterclockwise around rectangle  $BCEF$ , and this can end after 1, 2, or 3 additional vertices to  $B$  by traveling to D. So there are 7 total paths from B to D, which means  $4 \cdot 7 = 28$  paths from A to  $D$ .
- 20. C We will consider the paths of length 4 from A to D by whether they visit A or D in the middle of the path. There are a few cases:  $AXYZD$ ,  $AXAYD$ ,  $AXDYD$ , where X, Y, Z each represent one of B, C, E, F, not necessarily distinct. In the first case, there are 4 ways to select  $X$ , and 2 each to select  $Y$ ,  $Z$ . In the other cases, there are 4 ways each to select X and Y. This makes for a total of 48 paths.
- 21. D Without the loss of generality, we will consider the first path as  $AB$ . Then we can compute the number of circuits by when vertex  $D$  is reached. The cases are  $ABDXYZA, ABXDYZA, ABXYDZA,$  where X, Y, Z each represent one of C, E, F. This time, they do have to be distinct. Note that D cannot be the  $6<sup>th</sup>$  vertex reached, as there would be no path leading back to  $A$ . In the first case, there are 2 ways to select  $XYZ$ , specifically  $CEF$ ,  $FEC$ . In the second case, there are 2 ways to select  $X$ , and 2 ways to select  $YZ$ . In the third case, there are 2 ways to select  $XY$ , and 1 way to select Z. In total, there are 8 circuits starting with  $AB$ , and 24 ways to select equivalence of  $AB$ , for 192 circuits.
- 22. C By Pappus's Theorem, the  $V = 2\pi RA$ , where R is the distance from centroid of the region to the axis of revolution, and  $A$  is the area of the region. Thus the expected volume is  $\int_{-6}^{0} 2\pi (x_0 - x) A \cdot \frac{1}{6}$  $\frac{1}{6}$  dx, where  $x_0$  is the x-coordinate of the centroid. Since every quantity except  $(x_0 - x)$  is a constant in the integral, the expected volume can be rewritten as  $2\pi A \int_{-6}^{0} (x_0 - x) \cdot \frac{1}{6}$ 6  $\int_{-6}^{0} (x_0 - x) \cdot \frac{1}{6} dx$ .  $\int_{-6}^{0} (x_0 - x) \cdot \frac{1}{6}$ 6  $\int_{-6}^{0} (x_0 - x) \cdot \frac{1}{6} dx$  is the expected distance from centroid to axis of revolution, which occurs when the axis is located at  $x = -3$ . Thus it is sufficient to compute the volume of revolution when the axis is at  $x = -3$ , which is

$$
2\pi \int_0^1 (x+3) \left(x^{\frac{1}{3}} - x^2\right) dx = 2\pi \int_0^1 \left(-x^3 - 3x^2 + x^{\frac{4}{3}} + 3x^{\frac{1}{3}}\right) dx = \frac{20\pi}{7}
$$

23. D First, we need to determine the point on the graph where the tangent line has an xintercept of 1. Call that point  $\left(x,\frac{2}{3}\right)$  $\frac{2}{3}x^{\frac{3}{2}}$ , the slope of the tangent can be computed in two ways  $-f'(x) = x^{\frac{1}{2}}$ , and slope formula to (1, 0). Thus  $\frac{2}{3}$  $\frac{2}{3}x^{\frac{3}{2}}-0$  $\frac{x^{\overline{2}-0}}{x-1} = x^{\frac{1}{2}}$ . Solving to get  $x = 0, 3$ . When  $x > 3$ , the x-intercept will be greater than 1. However, the point is chosen on the curve, so the probability is the ratio of the arclength of the graph from 3 to 8 to the arclength from 0 to 8. Arclength from 3 to 8 can is  $\int_{3}^{8}$ ,  $\left(1 + (f'(x))\right)^2$  $\int_3^8 \sqrt{1 + (f'(x))^2} dx = \int_3^8 \sqrt{1 + x^2} dx$  $\int_3^8 \sqrt{1+x} \, dx = \left[\frac{2}{3}\right]$  $\frac{2}{3}(1+x)^{\frac{3}{2}}\Big]_3^8$ ଼  $=\frac{2}{3}$  $\frac{2}{3}(27-8) = \frac{38}{3}$  $\frac{3}{3}$ . Similarly, the arclength from 0 to 8 is  $\frac{2}{3}(27-1) = \frac{52}{3}$ .  $\frac{52}{3}$ . So the probability is  $\frac{38}{52} = \frac{19}{26}$  $\frac{19}{26}$ .

- 24. B There are 24 permutations each starting with A and E. Then there are 6 each starting with GA and GE. The  $60<sup>th</sup>$  permutation is the last one starting with GE, which is GEVSA.
- 25. C For  $f(x) = 0$  to have no solution, a is necessarily 0. Next,  $bx^2 + cx + d$  must have a negative discriminant, or  $c^2 - 4bd < 0$ . This cannot occur unless b, d are both positive or both negative. It is then simple enough to consider the 3 cases of 4bd. 4*bd* can be 4, 8, or 16, with probabilities of  $\frac{2}{25}$ ,  $\frac{4}{25}$  $\frac{4}{25}$ , and  $\frac{2}{25}$  respectively. When  $4bd =$ 4,  $c \neq \pm 2$ , or there would be a real solution. So  $bx^2 + cx + d$  has no real solution with probability  $\frac{2}{25} \cdot \frac{3}{5}$  $\frac{3}{5} + \frac{6}{25}$  $\frac{6}{25} = \frac{36}{125}$  $\frac{36}{125}$ . Add in the restriction of  $a = 0$  for a probability of ଷ  $\frac{36}{625}$ . However, the constant functions that slip through as they technically have a discriminant of 0 when treated as a quadratic. Four of the five constant functions do not have a solution, making the final probability  $\frac{40}{625} = \frac{8}{12!}$  $\frac{6}{125}$ .
- 26. C It is easier to compute this by complement. There are  $4^6$  6-letter sequences, of those  $4 \cdot 3^5$  do not contain any pair of consecutive letters that match.  $4^6 - 4 \cdot 3^5 =$  $4(1024 - 243) = 3124.$
- 27. A Call the 3 points chosen  $A, B, C$ , and place the circle centered at the origin, which we will call  $O$ . Without loss of generality, place  $A$  at  $(1, 0)$  by rotating the figure. Place  $\hat{B}$  in quadrants I or II by reflecting the figure, if necessary.  $\hat{C}$  has no restrictions when selected. Draw diameters through A and B. For  $\triangle ABC$  to be acute, C must be on the sector opposite of minor arc  $AB$ . Otherwise, one of the three central angles is greater than  $\pi$ , causing the corresponding inscribed angle to be obtuse. Let's call ∠ $AOB = x$ , then x is selected at random on [0,  $\pi$ ]. Let y be ∠ $AOC$ , but measured clockwise, rather than strictly the smallest angle between  $OA$  and  $OC$ . Then y is selected at random on [0,  $2\pi$ ].  $\triangle ABC$  is acute if  $\pi - x < y < \pi$ . We can now compute the probability geometrically.  $x, y$  are selected from a rectangle of dimensions  $\pi$  by  $2\pi$ .  $\Delta ABC$  is acute if the point is below  $y = \pi$  and above  $y = \pi - x$ , which compose of  $\frac{1}{4}$  of the rectangle.
- 28. C The area of the valid region described in #27 has an area of  $\frac{\pi^2}{2}$  $\frac{1}{2}$ , so each point within has a density of  $\frac{2}{\pi^2}$ . Next, we can compute the area of  $\triangle ABC$  in terms of x, y.  $[AOB] = \frac{1}{2}$  $\frac{1}{2}$ sin x,  $[ACC] = \frac{1}{2}$  $\frac{1}{2}$ sin y, and  $[BOC] = \frac{1}{2}$  $\frac{1}{2}\sin(2\pi - x - y) = -\frac{1}{2}$  $rac{1}{2}$ sin(x + y). Therefore,  $[ABC] = \frac{1}{2}$  $\frac{1}{2}(\sin x + \sin y - \sin(x + y)).$ The expected area of  $\triangle ABC$  is then  $\frac{2}{\pi^2} \cdot \frac{1}{2}$  $\frac{1}{2} \int_0^{\pi} \int_{\pi - x}^{\pi} (\sin x + \sin y - \sin(x + y)) dy dx$ Integrating the inner layer to get  $[y \sin x - \cos y + \cos(x + y)]_{\pi-x}^{\pi}$ . Working with each part:  $[y \sin x]_{\pi-x}^{\pi} = \sin x (\pi - (\pi - x)) = x \sin x$  $[-\cos y]_{\pi-x}^{\pi} = -\cos \pi + \cos(\pi - x) = 1 - \cos x$  $[\cos(x+y)]_{\pi-x}^{\pi} = \cos(x+\pi) - \cos(x+\pi-x) = -\cos x + 1$

Combining and placing it back in the outer layer to get:

 $\frac{1}{\pi^2} \int_0^{\pi} (x \sin x + 2 - 2 \cos x)$  $\int_0^{\pi} (x \sin x + 2 - 2 \cos x) dx = \frac{1}{\pi^2}$  $\frac{1}{\pi^2}[-x\cos x + \sin x + 2x - 2\sin x]_0^{\pi} = \frac{3\pi}{\pi^2} = \frac{3\pi}{\pi^2}$  $\frac{3}{\pi}$ .

- 29. B A randomly selected element is equally likely to be above or below the median. In each half, the expected selection is in the middle, at  $\frac{1}{4}$  or  $\frac{3}{4}$ .  $\frac{3}{4}$ . Both are  $\frac{1}{4}$  away from the median.
- 30. C Let the 3 elements chosen be  $x, y, z$ , each on [0, 1], so the sample space is a unit cube. Without loss of generality, let  $x < y < z$ . Since there are 3! =6 ordering of x, y, z, the selected case occupies a volume of  $\frac{1}{6}$ . We can simply treat the problem as selecting from that section, with each point  $(x, y, z)$  having a density of 6.  $y$  is the median of three, and its distance from the actual median is  $y - \frac{1}{3}$  $\frac{1}{2}$ . The expected distance is  $6 \int_0^1 \int_x^1 \int_y^1 \left| y - \frac{1}{2} \right|$  $\int_{\nu}^{1} |y - \frac{1}{2}|$  $\int_0^1 \int_x^1 \int_y^1 \left| y - \frac{1}{2} \right| dz dy dx = 6 \int_0^1 \int_x^1 \left| y - \frac{1}{2} \right|$  $\int_{0}^{1} |y - \frac{1}{2}| (1 - y)$  $\int_0^1 \int_x^1 \left| y - \frac{1}{2} \right| (1 - y) \, dy \, dx$ To compute the next layer, it is necessary to consider whether y is above or below  $\frac{1}{2}$ . Consequently, we must also break down the outer layer to whether  $x$  is above or below  $\frac{1}{5}$ . This makes for 3 cases:  $\mathbf{S}^{\prime}$  $\int_{\frac{1}{2}}^{1} \int_{\gamma}^{1} (y - \frac{1}{2})$  $\frac{1}{x}\left(y-\frac{1}{2}\right)(1-y)$  $\int_{\frac{1}{2}}^{1} \int_{x}^{1} \left( y - \frac{1}{2} \right) (1 - y) dy$ మ  $dx = \frac{1}{100}$  $rac{1}{192}$ భ

$$
\int_0^{\frac{1}{2}} \int_x^{\frac{1}{2}} \left(\frac{1}{2} - y\right) (1 - y) \, dy \, dx = \frac{1}{64}
$$
\n
$$
\int_0^{\frac{1}{2}} \int_0^{\frac{1}{2}} \left(y - \frac{1}{2}\right) (1 - y) \, dy \, dx = \frac{1}{96}
$$

Combining to get the expected value as  $6\left(\frac{1}{10}\right)$  $\frac{1}{192} + \frac{3}{192}$  $\frac{3}{192} + \frac{2}{192} = \frac{36}{192}$  $\frac{36}{192} = \frac{3}{16}$  $rac{5}{16}$ .
